

15: Lipids

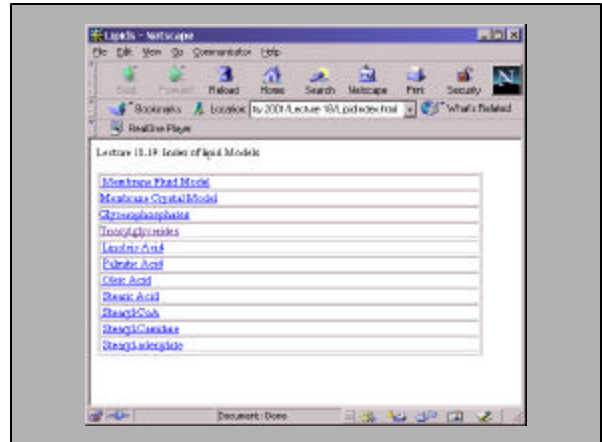

Compound	Formula	Oxidation Number
Carbon dioxide	<chem>O=C=O</chem>	4 (most oxidized)
Acetic acid	<chem>CC(=O)OH</chem>	3
Carbon monoxide	<chem>C#O</chem>	2
Formic acid	<chem>C=O</chem>	2
Acetone	<chem>CC(=O)C</chem>	2
Acetaldehyde	<chem>CC=O</chem>	1
Formaldehyde	<chem>C=O</chem>	0
Axylene	<chem>C#C#C</chem>	-1
Ethanol	<chem>CCO</chem>	-1
Ethene	<chem>C=C</chem>	-2
Ethane	<chem>CC</chem>	-3
Methane	<chem>C</chem>	-4 (least oxidized)

What makes a 'lipid'

- Hydrophobicity
- Functional definition
 - Large structural diversity
 - No oligomerized subunits
- Biological importance
 - Membranes
 - Energy metabolism
 - Intracellular signaling

C₁₈ Fatty Acids

- 18 carbon chains
 - a. stearic acid
 - b. oleic acid
 - c. linoleic acid
 - d. α-linolenic acid
- Δ⁹ structure
 - Most unsaturated
 - polyunsaturated

Triacylglycerols

- Fatty acid triesters of glycerol
- Most lipids exist as TAGs
 - Energy metabolism
 - More prevalent than membrane lipids

Hydrophobicity

Energy Metabolism

- Lipids are more reduced
- Higher enthalpy of combustion
 - Protein = 24 kJ g⁻¹
 - Carbo = 27 kJ g⁻¹
 - Lipid = 40 kJ g⁻¹
- Lipid stores in humans can provide enough energy to survive starvation for 2-3 months
- Liver glycogen stores are only sufficient for 1d

Glycerophospholipids

Single Micelle layer

Alignment of bilayer tails

Bilayer structures

Phospholipids

- model file: glycerophospholipid.pdb

Membranes: crystal

Membranes: fluid

Triacylglycerides

- 9,10-epoxy-12-hydroxyoctadecanoic acid-glycerotriester
- File: TAG.pdb

Lipid Droplets

- TAGs do not form an organized structure

Fatty Acid Oxidation

- 1. Lipase mediated hydrolysis of glycerol esters

Phospholipase A2

- Interfacial activation
- Conformational change opens hydrophobic core

Fatty acid binding proteins

- 2. Transport and handling
- Protein BP:
 - Increase FA aqueous solubility
 - Protect cellular components from detergent effects

Activation

- 3. Fatty Acids chemically modified
 - Signal structure
 - Hydrophilic 'handle'
- Structural Modification:
 - $\text{FA} + \text{CoA-SH} + \text{ATP} \rightarrow \text{FA-CoA} + \text{AMP} + \text{Pi}$

Fatty-acyl-CoA

• File: stearyl_coA.pdb

OK. Ready to go . . .

- The fatty acid in the cytoplasm has been activated
- Fatty acid oxidation occurs in the mitochondria to maximize the energy yield from the electron transfer reactions
- Just one small detail

Another modification

- Transesterification reaction has an equilibrium constant close to 1.0

Acyl-carnitine derivative

- Stearyl-carnitine

Carnitine Transporter

- The fatty-acyl-CoA structure is then regenerated on the matrix side
- CoA is not transported . . . why?

Fatty Acid Oxidation

- 1. Lipase mediated hydrolysis of glycerol esters
- Translocation
- Activation
- Mitochondrial uptake (carnitine transporter)

Fatty Acid β -Oxidation

- Step 1. Acyl-CoA Dehydrogenase:
 - α, β trans double bond
 - Flavoenzyme = FAD accepts e^-

β-Oxidation: step 3

- Re-hydrate the double bond on C_β
- Net: 1 NADH/H⁺

β-Oxidation: step 4

- Thiolysis at C_β
- FA-CoA, but 2 C shorter
- Net production of 1 AcCoA

Energy Metabolism

- Each round of β-oxidation produces:
 - 1 FADH₂
 - 1 NADH
 - 1 Acetyl-CoA
 - TCA cycle = 3 NADH + 1 FADH₂ + 1 GTP
- For palmitic acid (C16):
 - What is the total ATP yield?
- How many β-ox cycles?
- What is the total NADH yield?
- What is the total FADH₂ yield?
- What is the total GTP yield?
- What is the total ATP equivalent yield?
- Now subtract the 2 ATP used for fa-CoA formation.

Biosynthesis

- Building blocks
- ACOA synthesis
- Exchange

Modification of ACOA

- Carboxylation of ACOA to malonyl-CoA
 - First reaction commitment
 - Rate controlling step
- CO₂ fixation into a carbon chain

Activation of Malonyl-CoA

- Acyl-carrier protein (ACP) anchors synthesis

Activation of ACOA

- ACP is the handle
- Recognized by "Fatty Acid Synthase"

Condensation reaction

- Double carbonyl structure (β-keto group)
- Acetyl-ACP group is only used to start synthesis

β -keto Reduction

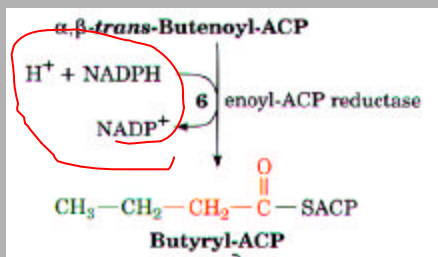

Dehydration

- Formation of α, β trans double bond

Alkene Reduction

- Formation of α, β alkane
- Next round: add another malonyl-CoA

Next Round

- Fatty acid chain elongation results in the new carbons being added from malonyl-CoA

Final Round

- The carboxyl group ends up on the end where the last carbon group was added
- Pathway for even-C chains
- What is the metabolic cost ?

Comparison of two pathways

- Same mechanism but different pathways

Other Lipids: Ketone Bodies

- Acetyl-CoA interconversion
- Diffusible through membranes
- Higher aqueous solubility

Other Lipids: Steroids

Cholesterol

Cholesterol

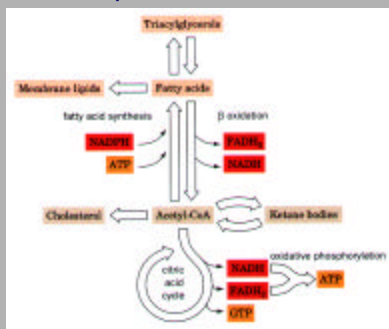

- All the carbon atoms are derived from acetate
- Complex synthesis from simple building block

Compound	Formula	Oxidation Number
Carbon dioxide	$O=C=O$	4 (most oxidized)
Acetic acid	$CH_3-C(=O)OH$	3
Carbon monoxide	$C \equiv O$	2
Formic acid	$H-C(=O)OH$	2
Acetone	$CH_3-C(=O)CH_3$	2
Acetaldehyde	$CH_3-C(=O)H$	1
Formaldehyde	$H-C(=O)H$	0
Acetylene	$HC \equiv CH$	-1
Ethanol	CH_3-CH_2-OH	-1
Ethene	$CH_2=CH_2$	-2
Ethane	CH_3-CH_3	-3
Methane	CH_4	-4 (least oxidized)

Lipid Metabolism

In terms of cellular energy, lipid metabolism is the primary determinant of metabolic organization
